	1. Inspecting transfusion.data file
	Blood transfusion saves lives - from replacing lost blood during major surgery or a serious injury to treating various illnesses and blood disorders. Ensuring that there's enough blood in supply whenever needed is a serious challenge for the health professionals. According to WebMD, "about 5 million Americans need a blood transfusion every year".  With blood donation written in it
	Our dataset is from a mobile blood donation vehicle in Taiwan. The Blood Transfusion Service Center drives to different universities and collects blood as part of a blood drive. We want to predict whether or not a donor will give blood the next time the vehicle comes to campus.  The data is stored in datasets/transfusion.data and it is structured according to RFMTC marketing model (a variation of RFM). We'll explore what that means later in this notebook. First, let's inspect the data.
In [3]:	<pre>%alias head powershell -command "&amp; {Get-Content %s -Head 5}" %head datasets/transfusion.data</pre> <pre>Poccess( months) Frequency (times) Manetary (s.c. blood) Time (months) "whether he (she denoted blood in March 2007"</pre>
	Recency (months),Frequency (times),Monetary (c.c. blood),Time (months),"whether he/she donated blood in March 2007" 2 ,50,12500,98 ,1 0 ,13,3250,28 ,1 1 ,16,4000,35 ,1 2 ,20,5000,45 ,1
	2. Loading the blood donations data
In [49]:	We now know that we are working with a typical CSV file (i.e., the delimiter is , , etc.). We proceed to loading the data into memory.  # Import pandas import pandas as pd
	# Read in dataset transfusion = pd.read_csv("datasets/transfusion.data")
	<pre># Print out the first rows of our dataset # YOUR CODE FOR TASK 2 print(transfusion.head())  Recency (months) Frequency (times) Monetary (c.c. blood) Time (months) \ </pre>
	0     2     50     12500     98       1     0     13     3250     28       2     1     16     4000     35       3     2     20     5000     45
	4 1 24 6000 77  whether he/she donated blood in March 2007 0 1 1
	2 3 4 0
	3. Inspecting transfusion DataFrame  Let's briefly return to our discussion of RFM model. RFM stands for Recency, Frequency and Monetary Value and it is commonly used in marketing for identifying your best customers. In our case, our customers are blood
	donors.  RFMTC is a variation of the RFM model. Below is a description of what each column means in our dataset:
	<ul> <li>R (Recency - months since the last donation)</li> <li>F (Frequency - total number of donation)</li> <li>M (Monetary - total blood donated in c.c.)</li> <li>T (Time - months since the first donation)</li> </ul>
	a binary variable representing whether he/she donated blood in March 2007 (1 stands for donating blood; 0 stands for not donating blood)  It looks like every column in our DataFrame has the numeric type, which is exactly what we want when building a machine learning model. Let's verify our hypothesis.
In [7]:	<pre># Print a concise summary of transfusion DataFrame # YOUR CODE FOR TASK 3 print(transfusion.info())</pre>
	<pre><class 'pandas.core.frame.dataframe'=""> RangeIndex: 748 entries, 0 to 747 Data columns (total 5 columns): # Column Non-Null Count Dtype</class></pre>
	0 Recency (months) 748 non-null int64 1 Frequency (times) 748 non-null int64 2 Monetary (c.c. blood) 748 non-null int64 3 Time (months) 748 non-null int64 4 whether he/she donated blood in March 2007 748 non-null int64
	dtypes: int64(5) memory usage: 29.3 KB None
	4. Creating target column  We are aiming to predict the value in whether he/she donated blood in March 2007 column. Let's rename this it to target so that it's more convenient to work with.
In [8]:	<pre># Rename target column as 'target' for brevity transfusion.rename(     columns={'whether he/she donated blood in March 2007': "target"},     inplace=True</pre>
	<pre># Print out the first 2 rows # YOUR CODE FOR TASK 4</pre>
	print(transfusion.head(2))  Recency (months) Frequency (times) Monetary (c.c. blood) Time (months) \ 0
	target 0 1 1 1
	5. Checking target incidence  We want to predict whether or not the same donor will give blood the next time the vehicle comes to campus. The model for this is a binary classifier, meaning that there are only 2 possible outcomes:
	<ul> <li>0 - the donor will not give blood</li> <li>1 - the donor will give blood</li> </ul>
In [9]:	Target incidence is defined as the number of cases of each individual target value in a dataset. That is, how many 0s in the target column compared to how many 1s? Target incidence gives us an idea of how balanced (or imbalanced) is our dataset.  # Print target incidence proportions, rounding output to 3 decimal places
Out[9]:	# YOUR CODE FOR TASK 5 transfusion.target.value_counts(normalize=True).round(3)  0 0.762
	1 0.238 Name: target, dtype: float64  6. Splitting transfusion into train and test datasets
	We'll now use train_test_split() method to split transfusion DataFrame.  Target incidence informed us that in our dataset 0 s appear 76% of the time. We want to keep the same structure in train and test datasets, i.e., both datasets must have 0 target incidence of 76%. This is very easy to do using
In [10]:	the train_test_split() method from the scikit learn library - all we need to do is specify the stratify parameter. In our case, we'll stratify on the target column.  # Import train_test_split method from sklearn.model_selection import train_test_split
	# Split transfusion DataFrame into # X_train, X_test, y_train and y_test datasets, # stratifying on the `target` column
	<pre>X_train, X_test, y_train , y_test = train_test_split(     transfusion.drop(columns='target'),     transfusion.target,     test_size=0.25,     random_state=42</pre>
	random_state=42, stratify=transfusion.target )  # Print out the first 2 rows of X_train
	<pre># YOUR CODE FOR TASK 6 print(X_train.head(2))  Recency (months) Frequency (times) Monetary (c.c. blood) Time (months) 334</pre>
	7. Selecting model using TPOT
	TPOT is a Python Automated Machine Learning tool that optimizes machine learning pipelines using genetic programming.  TPOT Machine Learning Pipeline
	TROT. The transfer Head of the State of the
	TPOT will automatically explore hundreds of possible pipelines to find the best one for our dataset. Note, the outcome of this search will be a scikit-learn pipeline, meaning it will include any pre-processing steps as well as the model.
